In the circuit shown in the figure, $R_1=R_2=R$, L is the self-inductance of the inductor. At time t=0 the switch S is closed. Right thereafter (i.e. at time t=0⁺) the current through R_1 is 3A. At a later time t₀ the current through R_2 is 2A. At that moment the switch S is opened again.

(a) Give an expression for t_0 in terms of R and L.

(b) Make an approximate graph of the current going through R_1 , I_{R1} , versus time. Use the convention that I_{R1} is positive at time t=0⁺. Indicate the scale on the I_{R1} axis. The time axis should start at 0, show t_0 , and go up to t larger than t_0 (e.g. $3t_0$). Indicate the magnitude of I_{R1} at time t= t_0^+ , i.e. right after S is opened again.

(c) At what time t>t₀ does I_{R1} have magnitude 1A? Give your answer in terms of t_0 .

Problem 2 (10 pts)

A 120 volt (rms), 60 Hz line provides power to a 75 watt light bulb.

(a) What is the resistance of the light bulb, in Ω ?

(b) By what factor will the brightness of the bulb change if a 5μ F capacitor is connected in series with the light bulb? Give the new power, in watts.

(c) Instead of connecting the capacitor, an inductor of inductance L is connected in series with the light bulb. If the brightness of the bulb changes by the same factor as in (b), what is the value of L, in H (henrys)?

(d) If now the capacitor of (b) and the inductor of (c) are connected in series with the lightbulb, by what factor will its brightness change from its original value (75W)? Give the new power, in watts. Justify your answer.

Problem 3 (10 pts)

A parallel plate capacitor with round plates of radius R=0.1 m and distance between plates 0.01m is connected to wires and discharging through a resistor. When the current through the resistor is 3A:

(a) What is the magnitude of the magnetic field at a distance 1cm from the wire far from the capacitor? Assume the wire is straight. Give your answer in G (Gauss) $(1T=10^4G)$.

(b) What is the magnitude of the magnetic field at a point midway between the capacitor plates at distance 1cm from the axis (line connecting the centers of the round plates)? Is it bigger, smaller or the same as that found in (a)? Give your answer in G.

(c) What is the value of dE/dt, the time derivative of the electric field between the capacitor plates? Give your answer in SI units (Volt/(meter)/seconds).
